Although the original purpose of SAMP is to communicate audio or visual information through a network or through other devices, nowadays it also has a versatile home networking function. In fact, the newest SAMP standards, SAMP3 and SAMP4, add a function to carry digital information in addition to the image and audio data, and therefore, the SAMP is also a communication standard for home networking. SAMP1 and SAMP2, being simpler, were first developed for home networking and then gradually expanded in performance and functions. The SAMP standard itself is divided into four layers: One layer is the physical layer (PHY), in which digital codes and control data are mapped onto analog signals that can be easily received by the same user device. Another is the link layer (LL), in which the ACK information (called the verify information in SAMP3) and its counterpart, the negative information known as the reset signal (RS in SAMP3), are exchanged for sequence control. Two more are the application layer (AL) and the service layer (SL), where the application codecs provide a home networking or communication function using a hub or a source device for audio and visual information. This application-specific layer is basically divided into the codec layer (AL) and the data layer (SL). The SAMP specifications (the latest version is SAMP4) are defined in the ITU-T document Q6/TS 29154 (the latest is B-ISDN Profile (tm) SAMP Application Protocol) as an amendment to the existing SAMP standards 1, 2 and 3. For some time already, the Internet, and its component protocols, has become an everyday working instrument of the business world. The Internet and its associated technology industries have also recently achieved impressive levels of growth. Companies find the medium useful and convenient, as well as a source of future revenues. In addition, companies need to equip themselves with the technology that has been developed to make the Internet useful as well as to protect themselves from risks. Currently, the Internet and its technology industries are in the process of developing new technologies. New technologies (such as video on demand, software as a service, big data, internet of things, and so on) continue to be developed. In addition, the Internet industry continues to grow and develop, which means that new security problems must

be solved. Although the Internet has become an everyday working instrument for companies,

SAMP is a proprietary data communication protocol which implements the SAMP Basic Profile, the SAMP Extended Profile as well as the SAMP Media Access Protocol. The SAMP Basic profile has been adopted by ISO (12352-2) and has been published in the SAMP Basic Profile document (ISBN 3-937356-96-7). The SAMP Extended Profile is a more general version of the SAMP Basic profile which has been published as ISO/IEC 11898-2. To the best of our knowledge, the SAMP hubs are distributed under the GNU Public License, and the application is free software. However, we could not verify this fact. The SAMP hub supports both the RTP (Real-time Transport Protocol) and RTCP (RTP Control Protocol) transport protocols. The SAMP standard (ID 12352-3) defines seven layers including a physical layer, a network layer, an addressing and encapsulation layer, a protocol data unit layer, a data transport and application layer, a quality of service layer and a signalling layer. The SAMP physical layer provides mechanisms to transport the data over serial lines. The SAMP addressing and encapsulation layer includes requirements for the addressing and encapsulation and defines seven operational modes in which addresses are interpreted. The protocol data unit layer defines packet formats and includes requirements for the following: acronymData exchanges and their semantics (described in chapter 4.1.1 of SAMP Basic profile (ISBN 3-937356-96-7)), frame formats (described in chapter 4.2.1 of SAMP Basic profile), network layer specifications (described in chapter 5 of SAMP Basic profile). The SAMP transport layer provides mechanisms to transport the packets over the network. The SAMP application layer provides transport services and has been defined as an application layer within the SAMP standard. The SAMP quality of service layer provides channel monitoring, is comprised of error management, buffer management, error recovery and timer management features. The signalling layer provides end-to-end signalling. In addition to the SAMP standard, a set of commands and structures has been defined. These are described in the SAMP command specification and related to basic operation, subscription information, request, pause/continue etc. JSAMP provides you with an SAMP hub implementation that you can use for your application. Therefore it is your responsibility to check the source code for the SAMP hub implementation provided by this package

You can use JSAMP with libsndfile for Open64, LibSndfile, mad, or QMAK Ogg is a free, open source, container format for storing media files. Ogg is a multi-purpose container format developed by the Xiph.org Foundation, designed to be simple to use and to allow a broad range of audio, video, and multimedia applications. Ogg is not a single application format, but rather a library of components to enable a broad range of applications, while providing functionality and portability not currently provided by any other current format. The format includes the Encapsulated XML (EXS) file format, a general streaming media file format, as well as the MOOG and Vorbis comments formats. The DualShock(tm) 3 wireless controller contains a force-feedback device (a.k.a. vibration motor) that allows games to react to the player's movements and provide more realistic tactile feedback. In addition, it provides a 2.4-inch LCD touch screen, four standard analog joysticks, and a four-way directional pad. Along with the Sony(R) PlayStation(R) 3, the DualShock(TM) 3 wireless controller is the centerpiece of the Sony(R) PlayStation(R) 3 platform, which is available today in North America. Java Sound is a Java library for managing digital audio. It includes classes, interfaces, and support for configuring and working with audio devices. The classes enable sample-based audio, managing buffers, frequency conversion, and providing hardware implementation for audio devices. The interfaces provide a common programming environment for audio applications. Support for configuring and working with audio devices is provided through four classes: AudioSystem, AudioBuffer, AudioInputStream, and AudioPlayer. EVAL is a 64-bit Java virtual machine built by the Lab for Validation of Alternative Languages. EVAL provides a wide range of capabilities that make it suitable for a variety of applications. The areas in which EVAL excels include areas where other systems can only perform poorly or cannot perform at all. EVAL is a very high-quality virtual machine with extensive hardware and system independence features. EVAL supports not only the Sun-developed 1.4-1.5 specifications but also the latest
